

## Luminous black holes

*Tuesday 9 August 2022 16:28 (3 minutes)*

A complimentary scenario to superradiance is presented based on the possible existence of instabilities in non-rotating black holes. A plausible parameter space for the formation of axion-type scalar field clouds around black holes in cosmological times is determined, which allows establishing bounds on the amount of dark matter as primordial black holes through axion-photon coupling. Additional phenomenological results are commented on.
