Motivation: Axions Well motivated extensions to SM

• QCD axion: solves strong CP problem

- Axions are quite generic in string models: "String axiverse"

$$V(\phi) \simeq m^2 f^2$$

Goldstone bosons, potential from nonperturbative breaking of symmetry

$$\left[1 - \cos\left(\frac{\phi}{f}\right)\right] \qquad \qquad \theta \equiv \frac{\phi}{f}$$

For QCD axion: $m^2 f^2 = \Lambda_{OCD}^4$

Motivation: Axions Well motivated extensions to SM

• QCD axion: solves strong CP problem

- Axions are quite generic in string models: "String axiverse"

 $V(\phi) \simeq m^2 f^2$

For QCD axion: $m^2 f^2 = \Lambda_{OCD}^4$ Decay constant f suppresses coupling to SM

Goldstone bosons, potential from nonperturbative breaking of symmetry

$$\left[1 - \cos\left(\frac{\phi}{f}\right)\right] \qquad \qquad \theta \equiv \frac{\phi}{f}$$

- Example: Single axion with potentia
- Misalignment: Initial angle randomly drawn from $\theta \in [-\pi, \pi]$
 - Typical initial energy density
- Homogeneous equation of motion:

ment axion cosmology
at
$$V(\phi) \simeq m^2 f^2 \left[1 - \cos\left(\frac{\phi}{f}\right) \right]$$

$$\rho \sim m^2 f^2$$

$$\partial_t^2 \Theta + 3H \partial_t \Theta + m^2 \sin \Theta = 0$$

- Example: Single axion with potentia
- Misalignment: Initial angle randomly drawn from $\theta \in [-\pi, \pi]$
 - Typical initial energy density $\rho \sim m^2 f^2$
- Homogeneous equation of motion: $\partial_t^2 \Theta + 3H \partial_t \Theta + m^2 \sin \Theta = 0$

- Field frozen until $H \sim m$, then begins damped oscillations
- Late-time solution during radiation domination: $\Theta(t) \propto \Theta_0 t^{-3/4} \cos(mt)$

ment axion cosmology
al
$$V(\phi) \simeq m^2 f^2 \left[1 - \cos\left(\frac{\phi}{f}\right) \right]$$

$$\rho \propto a^{-3}$$

Motivation: An axiverse Many axions

$$V(\phi_1, \dots \phi_N) = \sum_{i=1}^{M} \Lambda_i^4$$

 $\Lambda_i^4 \propto \Lambda_{IIV}^4 e^{-S_i}$

- Smooth spread in $S_i \Longrightarrow$ roughly log-flat distribution of axion masses
- Number of axions depends on topology, can easily be $\mathcal{O}(100)$

og-flat distribution of axion masses blogy, can easily be $\mathcal{O}(100)$

What are the dynamics and signatures of multiple axions in an axiverse?

Concrete example Focus on a single pair of coupled axions

$$V(\phi_L, \phi_S) = \Lambda_1^4 \left(1 - \cos\left(\frac{\phi_S}{f_S} + \frac{\phi_L}{f_L}\right) \right) + \Lambda_2^4 \left(1 - \cos\frac{\phi_L}{f_L}\right)$$
$$V(\theta_S, \theta_L) = m^2 f^2 \left[\left(1 - \cos(\theta_S + \theta_L)\right) + \mu^2 \mathscr{F}^2 \left(1 - \cos\theta_L\right) \right]$$

Short and Long refer to decay constants

Interesting new dynamics occur when $\mathscr{F}\gtrsim 3$ $0.7\lesssim\mu<1$

$$f \equiv f_S$$
 $\mathcal{F} \equiv \frac{f_L}{f_S}$ $\mu \equiv \frac{m_L}{m_S}$

Concrete example Focus on a single pair of coupled axions

$$V(\phi_L, \phi_S) = \Lambda_1^4 \left(1 - \cos\left(\frac{\theta_L}{2}\right) \right)$$
$$V(\theta_S, \theta_L) = m^2 f^2 \left[(1 - \cos\theta_L) \right]$$

Short and Long refer to decay constants

Interesting new dynamics occur when $\mathscr{F} \geq 3$

 $(\theta_S + \theta_L)) + \mu^2 \mathcal{F}^2 \left(1 - \cos \theta_L\right)$

 $f \equiv f_S$ $\mathscr{F} \equiv \frac{f_L}{f_S}$ $\mu \equiv \frac{m_L}{m_S}$

Homogeneous dynamics Review: Uncoupled axions

- Each axion begins with energy density $\rho \sim \mathcal{O}(m_i^2 f_i^2)$ with i = S, L
- For axions with similar masses, both enter horizon and begin redshifting at similar times

Homogeneous dynamics Review: Uncoupled axions

- Each axion begins with energy density $\rho \sim \mathcal{O}(m_i^2 f_i^2)$ with i = S, L
- For axions with similar masses, both enter horizon and begin redshifting at similar times

- Late times: long axion will dominate energy density by $\rho_L/\rho_S\sim \mathcal{F}^2$

Homogeneous dynamics **Coupled friendly axions**

- Axions are akin to coupled pendulums
- Long axion has larger decay constant \implies "more inertia"
 - Can drive short axion

Homogeneous dynamics **Coupled friendly axions**

- Axions are akin to coupled pendulums
- Long axion has larger decay constant \implies "more inertia"
 - Can drive short axion
- $\mu < 1$: long axion has smaller frequency

Coupled linear oscillators: resonance is <u>required</u> for significant energy transfer

Homogeneous dynamics **Coupled friendly axions**

- Axions are akin to coupled pendulums
- Long axion has larger decay constant \implies "more inertia"
 - Can drive short axion
- $\mu < 1$: long axion has smaller frequency
- Coupled linear oscillators: resonance is <u>required</u> for significant energy transfer
- Short axion can adjust its frequency by adjusting its amplitude
 - Adjust amplitude to achieve resonance and stay there: <u>autoresonance</u>

Autoresonance for Homogeneous Energy Densities

Autoresonance for Homogeneous Energy Densities

Resonance Curve of a Damped Pendulum

Homogeneous dynamics Key takeaways

- Axion dynamics are simply those of coupled nonlinear oscillators
- Analytically tractable
- Autoresonance can be quite generic provided the two axions are similar in mass ($0.7 \leq \mu < 1$)
 - $\mathcal{O}(1)$ of initial misalignment angles result in autoresonance

Implications for direct detection Review

• Axions generically couple to SM suppressed by decay constant f

• Haloscope experiments sensitive to $g_{a\gamma\gamma}^2 \rho_{axion}$

• Example: Axion-photon coupling $\mathscr{L} \supset -\frac{g_{a\gamma\gamma}}{\Delta}\phi F_{\mu\nu}\tilde{F}^{\mu\nu} = g_{a\gamma\gamma}\phi \vec{E} \cdot \vec{B}$ $g_{a\gamma\gamma} \sim \frac{\alpha}{4\pi f}$

Implications for direct detection Review: Detecting a lonely axion

• Uncoupled axion with potential $V(\phi) = m^2 f^2 (1 - \cos(\phi/f))$

$$\Omega_{axion} \approx 0.4 \left(\frac{\Theta_0}{\pi/2}\right)^2 \left(\frac{1}{1}\right)^2$$

 $\frac{m}{10^{-17}\,\mathrm{eV}}\right)^{1/2} \left(\frac{f}{10^{16}\,\mathrm{GeV}}\right)^2$

Implications for direct detection **Review: Detecting a lonely axion**

Uncoupled as

xion with potential
$$V(\phi) = m^2 f^2 (1 - \cos(\phi/f))$$

 $\Omega_{axion} \approx 0.4 \left(\frac{\Theta_0}{\pi/2}\right)^2 \left(\frac{m}{10^{-17} \,\mathrm{eV}}\right)^{1/2} \left(\frac{f}{10^{16} \,\mathrm{GeV}}\right)^2$

more weakly to SM. These two effects cancel exactly

$$\left(g_{a\gamma\gamma}^2 \frac{\rho_{axion}}{\rho_{DM}^0}\right)^{1/2} \sim 2.3 \times 10^{-17} \,\text{GeV}^{-1} \left(\frac{\Theta_0}{\pi/2}\right) \left(\frac{m}{10^{-7} \,\text{eV}}\right)^{1/4}$$
uncoupled

• Naïve misalignment: Axions with larger f have more energy density, but couple

long axion's energy density

• Short axion is typically coupled more strongly to SM, but can receive O(1) of

long axion's energy density

• Short axion is typically coupled more strongly to SM, but can receive O(1) of

long axion's energy density

- into account implies energy densities equalize for most $\mathcal{F} \lesssim 20$
- Look for long axion by resonant scanning over narrow mass range

• Short axion is typically coupled more strongly to SM, but can receive $\mathcal{O}(1)$ of

Long axion can be slightly harder to see, but properly taking inhomogeneities

long axion's energy density

- into account implies energy densities equalize for most $\mathcal{F} \leq 20$
- Look for long axion by resonant scanning over narrow mass range

• Short axion is typically coupled more strongly to SM, but can receive $\mathcal{O}(1)$ of

Long axion can be slightly harder to see, but properly taking inhomogeneities

• Boost to visibility even if the friendly pair are only a subcomponent of DM

Attractive Subcomponent Direct Detection Prospects

Beyond homogeneity What about spatial perturbations?

- During autoresonance, Θ_S is large \implies strong self-interactions
- Parametric resonant growth in spatial perturbations of short axion
 - Similar to large-misalignment scenarios [arXiv:1909.11665]

Beyond homogeneity What about spatial perturbations?

- During autoresonance, Θ_S is large \Longrightarrow strong self-interactions
- Parametric resonant growth in spatial perturbations of short axion
 - Similar to large-misalignment scenarios [arXiv:1909.11665]
- Length of time spent in parametric resonance controlled by $\mathcal{F} \equiv f_L / f_S$
- Small \mathcal{F} : Axion overdensities grow, lead to DM substructure
- Large \mathcal{F} : Overdensities grow nonperturbative, quench autoresonance

Beyond homogeneity

- Enhanced substructure on small scales depending on axion mass
- Halo mass $M_s \sim 12 M_{\odot} \left(\frac{10^{-17} \,\mathrm{eV}}{m} \right)$
- Direct/indirect detection
 - Transient events
 - Distant stars on critical lensing caustics
 - Correlated weak lensing distortions

Beyond homogeneity: Oscillon formation

Summary

- $\mathcal{O}(1)$ coincidences in mass and untuned initial conditions can lead to a new type of resonant energy transfer (intrinsically nonlinear)
- Not all axions in an axiverse will have a friend, but a friendly pair can be significantly more visibile to direct detection experiments
- If DM is a friendly pair, can get visible boosts to small-scale substructure
 - Dynamics and signatures are similar to large initial misalignment angles
 - Probes of DM substructure can test many axion models

Energy partition in nonperturbative regime

Gravitational indirect detection
