Measurement of the proton charge radius during the ULQ2 experiment

Since 2010, the proton charge radius has been measured using electron scattering, atomic and muonic hydrogen spectroscopy and the results of these measurements tend to fit with a 0.84-fm or 0.88-fm radius. The cause of the discrepancy is not fully understood but some inconsistent results are pointed out: different radii are determined from the same transition of the hydrogen atom (1S-3S) [1,2] and the electric form factor data obtained by the PRad and Mainz experiments using electron scattering are incompatible [3,4].

At ELPH, the ULQ2 (Ultra-Low Q^2) experiment aims at determining the proton charge radius using low-energy electron scattering ($E_e = 10\text{-}60$ MeV) covering the Q^2 range from 0.0003 (GeV/c)² to 0.008 (GeV/c)² as the proton charge radius is obtained from the slope of the proton electric form factor when the momentum transfer (Q^2) tends to 0. We are currently conducting the least model-dependent measurement of the proton charge radius with electron scattering as we are carrying out the absolute measurement of the electronproton scattering cross-section using a plastic (CH₂) target and the Rosenbluth separation in the extremely low Q^2 region. The equipment of the brand-new ULQ2 beam line has already been commissioned and the efficiency of the detectors have already been measured. The physics runs started last April and will be carried out for 28 days to determine the proton radius with 1% accuracy.

A novel approach for determining spatial moments of the proton charge density

The internal structure of the nucleon is a field of intensive study. This structure can be experimentally probed through electron elastic scattering off a proton target. This allows the extraction of the proton electric and the magnetic form factors which characterize the charge and the magnetization densities. The spatial moments of the proton charge density are extracted using the electric form factor (EFF) data. Up to now, methods rely on the evaluation of the EFF derivative in the limit of zero four-momentum transfer Q^2 enabling access only to positive even orders of spatial moments. A novel approach based on integral forms of the Fourier transform of the density function allows the determination of spatial moments of densities to any real valued order. Within this approach, we compute spatial moments of different orders from a reanalysis of EFF data obtained with Rosenbluth separation and from low Q^2 experiments covering a range of Q^2 from 2×10^{-4} up to 8.8 GeV^2 . We pay specific attention to the evaluation of systematic uncertainties. In this context, the evaluation of the proton charge radius corresponding to the second order moment of the proton charge density will be discussed.

Polarizability contribution to the hyperfine splitting in muonic deuterium from effective field theory

Muonic atom spectroscopy provides a precision probe of electroweak physics and possible sources of Beyond the Standard Model physics such as dark matter and the violation of lepton flavor universality. However, uncertainties from nuclear theory are the main bottleneck in calculations of the energy levels for muonic atoms. Therefore, it is necessary to reduce these uncertainties in order to correctly interpret possible new physics. In particular, the theoretical prediction of the nuclear polarizability that enters the two-photon exchange contribution to the energy levels must be improved. In recent years, a significant amount of progress has been made in regards to the two-photon exchange contribution to the Lamb shift in light muonic atoms using effective field theory techniques. Here, we use similar tools to investigate the polarizability contribution to the hyperfine splitting of muonic deuterium. We detail the generic formalism used to extract the hyperfine splitting and employ forces and currents derived in chiral effective field theory.

Precision Measurements with Simple Molecular Hydrogen Ions at ALPHATRAP

Molecular hydrogen ions offer a unique opportunity for testing fundamental physics at high precision. As simple three-body systems, the energy levels and properties of H_2^+ , and its isotopologue HD^+ , are exactly calculable and precision spectroscopy enables measurement of fundamental constants such as the proton-to-electron mass ratio [1], including possible temporal or spatial variation [2]. In contrast to atomic hydrogen, molecular hydrogen ions have many narrow, laser-accessible transitions and can be trapped and cooled ion traps. This offers not only exciting prospects for metrology [3], but presents a viable method for creating and performing precision measurements on the antimatter counterpart [4]. We have recently demonstrated long-term trapping and quantum control a single HD^+ molecule in the rovibrational ground state at the ALPHATRAP Penning-trap apparatus [5] culminating in a measurement of the ground state hyperfine structure. This measurement allows us to extract the shielded g -factors of the proton, deuteron, and electron along with the E_4 and E_5 coefficients of the hyperfine Hamiltonian and demonstrates molecular state detection via the continuous Stern-Gerlach effect which we will use in upcoming measurements of rovibrational transitions in HD^+ and H_2^+ .

Measurement of Compton scattering at MAMI and extraction of nucleon polarizabilities

Polarizabilities are fundamental properties related to the internal dynamics of the nucleon. They play a crucial role not only in our understanding of the nucleon, but also in other areas such as precision atomic physics. The experimental program performed by the A2 Collaboration at the MAMI accelerator facility in Mainz aims for an accurate extraction of the nucleon polarizabilities using Compton scattering on nucleons. Recently, the A2 Collaboration at MAMI measured the unpolarized cross-section and the beam asymmetry Σ_3 for Compton scattering below pion photoproduction threshold with unprecedented precision. This measurement allowed accurate extraction of the proton scalar polarizabilities based only on this new data set. Moreover, for the extraction of the spin polarizabilities, the beam asymmetry Σ_3 and the beam-target asymmetries $\Sigma_{2,x}$ and $\Sigma_{2,z}$ were measured at energies above pion production threshold, where the sensitivity to the spin polarizabilities increases. Presently, the A2 Collaboration plans a high-precision measurement of the neutron polarizabilities using Compton scattering on light nuclei with novel experimental technique, exploiting an active target in combination with the Crystal Ball/TAPS setup. In this talk, the current results and the plans for the upcoming measurements with the A2 setup at MAMI will be presented.

Tests of mu-e universality

Lepton universality (LU) typically refers to the lepton coupling, which is considered to be the same for all charged leptons, if the interaction is electroweak according to the Standard Model.

Lepton universality tests are hence a compelling probe for New Physics.

I will review the current status of mu-e universality and recent testing efforts, with some emphasis on TREK/E36 at J-PARC and MUSE at PSI.

The MUSE experiment

The MUon proton Scattering Experiment (MUSE) at the PiM1 beam line of the Paul Scherrer Institute was created a decade ago in response to the Proton Radius Puzzle, the difference observed between muonic hydrogen measurements of the proton charge radius and the existing electronic measurements. To date, MUSE has commissioned its experimental systems to the level needed for the measurements and performed a careful studies of the electron and muon beam properties in the PiM1 channel. MUSE already obtained scattering data sets at 3 different beam momenta: ± 115 MeV/c, ± 160 MeV/c and ± 210 MeV/c in 2021 and 2022. Now MUSE is simultaneously measuring the elastic scattering of electrons and muons from a liquid hydrogen target to increase the statistics of those data sets. Both beam polarities are being measured over the course of the experiment. By comparing the four scattering cross sections, the experiment will provide unique muon proton scattering data with a precision sufficient to address the proton radius puzzle and will directly measure two-photon exchange (TPE) effects for both muons and electrons.

The MUSE experiment is supported by the US Department of Energy, NSF, PSI, and the US-Israel Binational Science Foundation.
